

Rust Language Cheat Sheet

08.02.2020

Contains clickable links to [The Book](#) BK, [Rust by Example](#) EX, [Std Docs](#) STD, [Nomicon](#) NOM, [Reference](#) REF. Other symbols used: largely **deprecated** ☒, has a **minimum edition** ¹⁸ ‘18, is **work in progress** 🚧, or **bad** 🔴.

[Fira Code Ligatures](#) (`==`, `⇒`) [Night Mode](#) 💡

Data Structures

Data types and memory locations defined via keywords.

Example	Explanation
<code>struct S { }</code>	Define a struct <small>BK EX STD REF</small> with named fields.
<code>struct S { x: T }</code>	Define struct with named field <code>x</code> of type <code>T</code> .
<code>struct S (T);</code>	Define "tupled" struct with numbered field <code>.0</code> of type <code>T</code> .
<code>struct S;</code>	Define zero sized <small>NOM</small> unit struct. Occupies no space, optimized away.
<code>enum E { }</code>	Define an enum <small>BK EX REF</small> , c. algebraic data types, tagged unions .
<code>enum E { A, B(), C {} }</code>	Define variants of enum; can be unit- <code>A</code> , tuple- <code>B()</code> and struct-like <code>C{}</code> .
<code>enum E { A = 1 }</code>	If variants are only unit-like, allow discriminant values, e.g., for FFI.
<code>union U { }</code>	Unsafe C-like union <small>REF</small> for FFI compatibility.
<code>static X: T = T();</code>	Global variable <small>BK EX REF</small> with <code>'static</code> lifetime, single memory location.
<code>const X: T = T();</code>	Defines constant <small>BK EX REF</small> . Copied into a temporary when used.
<code>let x: T;</code>	Allocate <code>T</code> bytes on stack ¹ bound as <code>x</code> . Assignable once, not mutable.
<code>let mut x: T;</code>	Like <code>let</code> , but allow for mutability and mutable borrow. ²
<code>x = y;</code>	Moves <code>y</code> to <code>x</code> , invalidating <code>y</code> if <code>T</code> is not <code>Copy</code> , and copying <code>y</code> otherwise.

¹ They live on the stack for synchronous code. For `async` code these variables become part of the `async`'s state machine which may ultimately reside on the heap.

² Note that technically *mutable* and *immutable* are a bit of a misnomer. Even if you have an immutable binding or shared reference, it might contain a `Cell`, which supports so called *interior mutability*.

Creating and accessing data structures; and some more *sigilic* types.

Example	Explanation
<code>S { x: y }</code>	Create <code>struct S { } or use'ded enum E::S { }</code> with field <code>x</code> set to <code>y</code> .
<code>S { x }</code>	Same, but use local variable <code>x</code> for field <code>x</code> .
<code>S { ..s }</code>	Fill remaining fields from <code>s</code> , esp. useful with <code>Default</code> .
<code>S { 0: x }</code>	Like <code>s(x)</code> below, but set field <code>.0</code> with struct syntax.
<code>S(x)</code>	Create <code>struct S(T) or use'ded enum E::S() with field .0 set to x.</code>

Example	Explanation
s	If s is unit <code>struct S</code> ; or <code>use</code> 'ed <code>enum E::S</code> create value of s.
E::C { x: y }	Create enum variant c. Other methods above also work.
()	Empty tuple, both literal and type, aka unit . <small>STD</small>
(x)	Parenthesized expression.
(x,)	Single-element tuple expression. <small>EX STD REF</small>
(s,)	Single-element tuple type.
[s]	Array type of unspecified length, i.e., slice . <small>STD EX REF</small> Can't live on stack. *
[s; n]	Array type <small>EX STD</small> of fixed length n holding elements of type s.
[x; n]	Array instance with n copies of x. <small>REF</small>
[x, y]	Array instance with given elements x and y.
x[0]	Collection indexing. Overloadable <code>Index</code> , <code>IndexMut</code>
x[..]	Collection slice-like indexing via <code>RangeFull</code> , c. slices.
x[a ..]	Collection slice-like indexing via <code>RangeFrom</code> .
x[.. b]	Collection slice-like indexing <code>RangeTo</code> .
x[a .. b]	Collection slice-like indexing via <code>Range</code> .
a .. b	Right-exclusive range <small>REF</small> creation, also seen as .. b.
a == b	Inclusive range creation, also seen as == b.
s.x	Named field access , <small>REF</small> might try to <code>Deref</code> if x not part of type s.
s.0	Numbered field access, used for tuple types s (T).

* For now, see [tracking issue](#) and corresponding [RFC 1909](#).

References & Pointers

Granting access to un-owned memory. Also see section on Generics & Constraints.

Example	Explanation
&s	Shared reference <small>BK STD NOM REF</small> (space for holding <i>any</i> &s).
&[s]	Special slice reference that contains (address, length).
&str	Special string reference that contains (address, length).
&dyn s	Special trait object <small>BK</small> reference that contains (address, vtable).
&mut s	Exclusive reference to allow mutability (also <code>&mut [s]</code> , <code>&mut dyn S, ...</code>)
*const s	Immutable raw pointer type <small>BK STD REF</small> w/o memory safety.
*mut s	Mutable raw pointer type w/o memory safety.
&s	Shared borrow <small>BK EX STD</small> (e.g., address, len, vtable, ... of <i>this</i> s, like <code>0x1234</code>).
&mut s	Exclusive borrow that allows mutability . <small>EX</small>
ref s	Bind by reference. <small>EX</small>
*r	Dereference <small>BK STD NOM</small> a reference r to access what it points to.
*r = s;	If r is a mutable reference, move or copy s to target memory.
s = *r;	Make s a copy of whatever r references, if that is Copy.
s = *my_box;	Special case for Box that can also move out Box'ed content if it isn't Copy.
'a	A lifetime parameter , <small>BK EX NOM REF</small> , duration of a flow in static analysis.

Example	Explanation
<code>&'a S</code>	Only accepts a <code>S</code> with an address that lives <code>'a</code> or longer.
<code>&'a mut S</code>	Same, but allow content of address to be changed.
<code>struct S<'a> {}</code>	Signals <code>S</code> will contain address with lifetime <code>'a</code> . Creator of <code>S</code> decides <code>'a</code> .
<code>trait T<'a> {}</code>	Signals a <code>S</code> which <code>impl T</code> for <code>S</code> might contain address.
<code>fn f<'a>(t: &'a T)</code>	Same, for function. Caller decides <code>'a</code> .
<code>'static</code>	Special lifetime lasting the entire program execution.

Functions & Behavior

Define units of code and their abstractions.

Example	Explanation
<code>trait T {}</code>	Define a trait ; <small>BK EX REF</small> common behavior others can implement.
<code>trait T : R {}</code>	<code>T</code> is substrate of supertrait <small>REF</small> <code>R</code> . Any <code>S</code> must <code>impl R</code> before it can <code>impl T</code> .
<code>impl S {}</code>	Implementation <small>REF</small> of functionality for a type <code>S</code> , e.g., methods.
<code>impl T for S {}</code>	Implement trait <code>T</code> for type <code>S</code> .
<code>impl !T for S {}</code>	Disable an automatically derived auto trait <small>NOM REF</small> .
<code>fn f() {}</code>	Definition of a function <small>BK EX REF</small> ; or associated function if inside <code>impl</code> .
<code>fn f() -> S {}</code>	Same, returning a value of type <code>S</code> .
<code>fn f(&self) {}</code>	Define a method, e.g., within an <code>impl S {}</code> .
<code>const fn f() {}</code>	Constant <code>fn</code> usable at compile time, e.g., <code>const X: u32 = f(Y).</code> ¹⁸
<code>async fn f() {}</code>	Async ¹⁸ function transformation, makes <code>f</code> return an <code>impl Future</code> . <small>STD</small>
<code>async fn f() -> S {}</code>	Same, but make <code>f</code> return an <code>impl Future<Output=S></code> .
<code>async { x }</code>	Used within a function, make <code>{ x }</code> an <code>impl Future<Output=X></code> .
<code>fn() -> S</code>	Function pointers , <small>BK STD REF</small> , memory holding address of a callable.
<code>Fn() -> S</code>	Callable Trait , <small>BK STD</small> (also <code>FnMut</code> , <code>FnOnce</code>), implemented by closures, <code>fn's</code> ...
<code> {}</code>	A closure <small>BK EX REF</small> that borrows its captures.
<code> x {}</code>	Closure with a bound parameter <code>x</code> .
<code> x x + x</code>	Closure without block expression; may only consist of single expression.
<code>move x x + y</code>	Closure taking ownership of its captures.
<code>return true</code>	Closures sometimes look like logical ORs (here: return a closure).
<code>unsafe {}</code>	If you enjoy debugging segfaults Friday night; unsafe code . <small>BK EX NOM REF</small>

Control Flow

Control execution within a function.

Example	Explanation
<code>while x {}</code>	Loop <small>REF</small> , run while expression <code>x</code> is true.
<code>loop {}</code>	Loop infinitely <small>REF</small> until <code>break</code> . Can yield value with <code>break x</code> .
<code>for x in iter {}</code>	Syntactic sugar to loop over iterators . <small>BK STD REF</small>
<code>if x {} else {}</code>	Conditional branch <small>REF</small> if expression is true.
<code>'label: loop {}</code>	Loop label <small>EX REF</small> , useful for flow control in nested loops.

Example	Explanation
<code>break</code>	Break expression REF to exit a loop.
<code>break x</code>	Same, but make <code>x</code> value of the loop expression (only in actual <code>loop</code>).
<code>break 'label</code>	Exit not only this loop, but the enclosing one marked with <code>'label</code> .
<code>continue</code>	Continue expression REF to the next loop iteration of this loop.
<code>continue 'label</code>	Same, but instead of enclosing loop marked with <code>'label</code> .
<code>x?</code>	If <code>x</code> is <code>Err</code> or <code>None</code> , return and propagate . BK EX STD REF
<code>x.await</code>	Only works inside <code>async</code> . Yield flow until <code>Future</code> or <code>Stream</code> [?] <code>x</code> ready. ¹⁸
<code>return x</code>	Early return from function. More idiomatic way is to end with expression.
<code>f()</code>	Invoke callable <code>f</code> (e.g., a function, closure, function pointer, <code>Fn</code> , ...).
<code>x.f()</code>	Call member function, requires <code>f</code> takes <code>self</code> , <code>&self</code> , ... as first argument.
<code>X::f(x)</code>	Same as <code>x.f()</code> . Unless <code>impl</code> Copy for <code>X {}</code> , <code>f</code> can only be called once.
<code>X::f(&x)</code>	Same as <code>x.f()</code> .
<code>X::f(&mut x)</code>	Same as <code>x.f()</code> .
<code>S::f(&x)</code>	Same as <code>x.f()</code> if <code>x</code> derefs to <code>S</code> , i.e., <code>x.f()</code> finds methods of <code>S</code> .
<code>T::f(&x)</code>	Same as <code>x.f()</code> if <code>x</code> <code>impl</code> <code>T</code> , i.e., <code>x.f()</code> finds methods of <code>T</code> if in scope.
<code>X::f()</code>	Call associated function, e.g., <code>X::new()</code> .
<code><X as T>::f()</code>	Call trait method <code>T::f()</code> implemented for <code>X</code> .

Organizing Code

Segment projects into smaller units and minimize dependencies.

Example	Explanation
<code>mod m {}</code>	Define a module BK EX REF , get definition from inside {}.
<code>mod m;</code>	Define a module, get definition from <code>m.rs</code> or <code>m/mod.rs</code> .
<code>a::b</code>	Namespace path EX REF to element <code>b</code> within <code>a</code> (<code>mod</code> , <code>enum</code> , ...).
<code>::b</code>	Search <code>b</code> relative to crate root.
<code>crate::b</code>	Search <code>b</code> relative to crate root. ¹⁸
<code>self::b</code>	Search <code>b</code> relative to current module.
<code>super::b</code>	Search <code>b</code> relative to parent module.
<code>use a::b;</code>	Use EX REF <code>b</code> directly in this scope without requiring <code>a</code> anymore.
<code>use a::{b, c};</code>	Same, but bring <code>b</code> and <code>c</code> into scope.
<code>use a::b as x;</code>	Bring <code>b</code> into scope but name <code>x</code> , like <code>use std::error::Error as E</code> .
<code>use a::b as _;</code>	Bring <code>b</code> anonymously into scope, useful for traits with conflicting names.
<code>use a::*; </code>	Bring everything from <code>a</code> into scope.
<code>pub use a::b;</code>	Bring <code>a::b</code> into scope and reexport from here.
<code>pub T</code>	"Public if parent path is public" visibility BK for <code>T</code> .
<code>pub(crate) T</code>	Visible at most in current crate.
<code>pub(self) T</code>	Visible at most in current module.
<code>pub(super) T</code>	Visible at most in parent.
<code>pub(in a::b) T</code>	Visible at most in <code>a::b</code> .

Example	Explanation
<code>extern crate a;</code>	Declare dependency on external crate BK EX REF ; just <code>use a::b</code> in ¹⁸ .
<code>extern "C" {}</code>	Declare external dependencies and ABI (e.g., "C") from FFI . BK EX NOM REF
<code>extern "C" fn f() {}</code>	Define function to be exported with ABI (e.g., "C") to FFI.

Type Aliases and Casts

Short-hand names of types, and methods to convert one type to another.

Example	Explanation
<code>type T = S;</code>	Create a type alias BK REF , i.e., another name for S.
<code>Self</code>	Type alias for implementing type REF , e.g. <code>fn new() -> Self</code> .
<code>self</code>	Method subject in <code>fn f(self) {}</code> , same as <code>fn f(self: Self) {}</code> .
<code>&self</code>	Same, but refers to self as borrowed, same as <code>f(self: &Self)</code>
<code>&mut self</code>	Same, but mutably borrowed, same as <code>f(self: &mut Self)</code>
<code>self: Box<Self></code>	Arbitrary self type, add methods to smart pointers (<code>my_box.f_of_self()</code>).
<code>S as T</code>	Disambiguate BK REF type S as trait T, e.g., <code><X as T>::f()</code> .
<code>S as R</code>	In <code>use</code> of symbol, import S as R, e.g., <code>use a::b as x</code> .
<code>x as u32</code>	Primitive cast EX REF , may truncate and be a bit surprising. NOM

Macros & Attributes

Code generation constructs expanded before the actual compilation happens.

Example	Explanation
<code>m!()</code>	Macro BK STD REF invocation, also <code>m![]</code> , <code>m![]</code> (depending on macro).
<code>\$x:ty</code>	Macro capture, also <code>\$x:expr</code> , <code>\$x:ty</code> , <code>\$x:path</code> , ... see next table.
<code>\$x</code>	Macro substitution in macros by example . BK EX REF
<code>\$(x),*</code>	Macro repetition "zero or more times" in macros by example.
<code>\$(x),?</code>	Same, but "zero or one time".
<code>\$(x),+</code>	Same, but "one or more times".
<code>\$(x)<<+</code>	In fact separators other than , are also accepted. Here: <<.
<code>\$crate</code>	Special hygiene variable, crate where macros is defined. ?
<code>#[attr]</code>	Outer attribute . EX REF , annotating the following item.
<code>#![attr]</code>	Inner attribute, annotating the surrounding item.

In a `macro_rules!` implementation, the following macro captures can be used:

Macro Capture	Explanation
<code>\$x:item</code>	An item, like a function, struct, module, etc.
<code>\$x:block</code>	A block {} of statements or expressions, e.g., <code>{ let x = 5; }</code>
<code>\$x:stmt</code>	A statement, e.g., <code>let x = 1 + 1;</code> , <code>String::new()</code> ; or <code>vec![]</code> ;
<code>\$x:expr</code>	An expression, e.g., <code>x</code> , <code>1 + 1</code> , <code>String::new()</code> or <code>vec![]</code>
<code>\$x:pat</code>	A pattern, e.g., <code>Some(t)</code> , <code>(17, 'a')</code> or <code>_</code> .
<code>\$x:ty</code>	A type, e.g., <code>String</code> , <code>usize</code> or <code>Vec<u8></code> .

Macro Capture	Explanation
\$x:ident	An identifier, for example in <code>let x = 0</code> ; the identifier is <code>x</code> .
\$x:path	A path (e.g. <code>foo</code> , <code>::std::mem::replace</code> , <code>transmute::<_, int></code> , ...).
\$x:literal	A literal (e.g. <code>3</code> , <code>"foo"</code> , <code>b"bar"</code> , etc.).
\$x:meta	A meta item; the things that go inside <code>#[...]</code> and <code>#![...]</code> attributes.
\$x:tt	A single token tree, see here for more details.

Pattern Matching

Constructs found in `match` or `let` expressions, or function parameters.

Example	Explanation
<code>match m { }</code>	Initiate pattern matching BK EX REF , then use match arms, c. next table.
<code>let s(x) = get();</code>	Notably, <code>let</code> also pattern matches similar to the table below.
<code>let s { x } = s;</code>	Only <code>x</code> will be bound to value <code>s.x</code> .
<code>let (_, b, _) = abc;</code>	Only <code>b</code> will be bound to value <code>abc.1</code> .
<code>let (a, ...) = abc;</code>	Ignoring 'the rest' also works.
<code>let Some(x) = get();</code>	Won't work  if pattern can be refuted REF , use <code>if let</code> instead.
<code>if let Some(x) = get() {}</code>	Branch if pattern can actually be assigned (e.g., <code>enum</code> variant).
<code>fn f(s { x }: s)</code>	Function parameters also work like <code>let</code> , here <code>x</code> bound to <code>s.x</code> of <code>f(s)</code> .

Pattern matching arms in `match` expressions. The left side of these arms can also be found in `let` expressions.

Example	Explanation
<code>E :: A => {}</code>	Match enum variant <code>A</code> , c. pattern matching . BK EX REF
<code>E :: B (..) => {}</code>	Match enum tuple variant <code>B</code> , wildcard any index.
<code>E :: C { .. } => {}</code>	Match enum struct variant <code>C</code> , wildcard any field.
<code>S { x: 0, y: 1 } => {}</code>	Match struct with specific values (only accepts <code>s</code> with <code>s.x</code> of <code>0</code> and <code>s.y</code> of <code>1</code>).
<code>S { x: a, y: b } => {}</code>	Match struct with <i>any(!)</i> values and bind <code>s.x</code> to <code>a</code> and <code>s.y</code> to <code>b</code> .
<code>S { x, y } => {}</code>	Same, but shorthand with <code>s.x</code> and <code>s.y</code> bound as <code>x</code> and <code>y</code> respectively.
<code>S { .. } => {}</code>	Match struct with any values.
<code>D => {}</code>	Match enum variant <code>E :: D</code> if <code>D</code> in <code>use</code> .
<code>D => {}</code>	Match anything, bind <code>D</code> ; possibly false friend  of <code>E :: D</code> if <code>D</code> not in <code>use</code> .
<code>_ => {}</code>	Proper wildcard that matches anything / "all the rest".
<code>(a, 0) => {}</code>	Match tuple with any value for <code>a</code> and <code>0</code> for second.
<code>[a, 0] => {}</code>	Slice pattern , REF  match array with any value for <code>a</code> and <code>0</code> for second.
<code>[1, ..] => {}</code>	Match array starting with <code>1</code> , any value for rest; subslice pattern . 
<code>[2, .., 5] => {}</code>	Match array starting with <code>1</code> , ending with <code>5</code> . 
<code>[2, x @ .., 5] => {}</code>	Same, but also bind <code>x</code> to slice representing middle (c. next entry). 
<code>x @ 1..=5 => {}</code>	Bind matched to <code>x</code> ; pattern binding , BK EX REF here <code>x</code> would be <code>1, 2, ... or 5</code> .
<code>0 1 => {}</code>	Pattern alternatives (or-patterns).
<code>E :: A E :: Z</code>	Same, but on enum variants.
<code>E :: C {x} E :: D {x}</code>	Same, but bind <code>x</code> if all variants have it.

Example	Explanation
<code>S { x } if x > 10</code>	Pattern match guards , <small>BK EX REF</small> condition must be true as well to match.

Generics & Constraints

Generics combine with many other constructs such as `struct S<T>`, `fn f<T>()`, ...

Example	Explanation
<code>S<T></code>	A generic <small>BK EX</small> type with a type parameter (<code>T</code> is placeholder name here).
<code>S<T: R></code>	Type short hand trait bound <small>BK EX</small> specification (<code>R</code> <i>must</i> be actual trait).
<code>T: R, P: S</code>	Independent trait bounds (here one for <code>T</code> and one for <code>P</code>).
<code>T: R, S</code>	Compile error you probably want compound bound <code>R + S</code> below.
<code>T: R + S</code>	Compound trait bound <small>BK EX</small> , <code>T</code> must fulfill <code>R</code> and <code>S</code> .
<code>T: R + 'a</code>	Same, but w. lifetime. <code>T</code> must fulfill <code>R</code> , if <code>T</code> has lifetimes, must outlive <code>'a</code> .
<code>T: ?Sized</code>	Opt out of a pre-defined trait bound, here <code>Sized</code> .?
<code>T: 'a</code>	Type lifetime bound <small>EX</small> ; if <code>T</code> has references, they must outlive <code>'a</code> .
<code>'b: 'a</code>	Lifetime <code>'b</code> must live at least as long as (i.e., <i>outlive</i>) <code>'a</code> bound.
<code>S<T> where T: R</code>	Same as <code>S<T: R></code> but more pleasant to read for longer bounds.
<code>S<T = R></code>	Default type parameter <small>BK</small> for associated type.
<code>S<'_></code>	Inferred anonymous lifetime ; asks compiler to <i>'figure it out'</i> if obvious.
<code>S<'_></code>	Inferred anonymous type , e.g., as <code>let x: Vec<'_> = iter.collect()</code>
<code>S::<T></code>	Turbofish <small>STD</small> call site type disambiguation, e.g. <code>f::<u32>()</code> .
<code>trait T<X> {}</code>	A trait generic over <code>X</code> . Can have multiple <code>impl T for S</code> (one per <code>X</code>).
<code>trait T { type X; }</code>	Defines associated type <small>BK REF</small> <code>X</code> . Only one <code>impl T for S</code> possible.
<code>type X = R;</code>	Set associated type within <code>impl T for S { type X = R; }</code> .
<code>impl<T> S<T> {}</code>	Implement functionality for any <code>T</code> in <code>S<T></code> .
<code>impl S<T> {}</code>	Implement functionality for exactly <code>S<T></code> (e.g., <code>S<u32></code>).
<code>fn f() -> impl T</code>	Existential types <small>BK</small> , returns an unknown-to-caller <code>s</code> that <code>impl T</code> .
<code>fn f(x: &impl T)</code>	Trait bound, "impl traits" <small>BK</small> , somewhat similar to <code>fn f<S:T>(x: &S)</code> .
<code>fn f(x: &dyn T)</code>	Marker for dynamic dispatch <small>BK REF</small> , <code>f</code> will not be monomorphized.
<code>fn f() where Self: R</code>	In a <code>trait T {}</code> , mark <code>f</code> as accessible only on types that also <code>impl R</code> .
<code>for<'a></code>	Higher-ranked trait bounds. <small>NOM REF</small>
<code>trait T: for<'a> R<'a> {}</code>	Any <code>s</code> that <code>impl T</code> would also have to fulfill <code>R</code> for any lifetime.

Strings & Chars

Rust has several ways to create string or char literals, depending on your needs.

Example	Explanation
<code>" ... "</code>	String literal , <small>REF</small> UTF-8, will interpret <code>\n</code> as <i>line break</i> <code>0xA</code> , ...
<code>r" ... "</code> ,	Raw string literal , <small>REF</small> UTF-8, won't interpret <code>\n</code> , ...
<code>r#" ... "#, etc.</code>	Raw string literal, UTF-8, but can also contain <code>"</code> .
<code>b" ... "</code>	Byte string literal ; <small>REF</small> constructs ASCII <code>[u8]</code> , not a string.
<code>br" ... ", br#" ... "#, etc.</code>	Raw byte string literal, ASCII <code>[u8]</code> , combination of the above.

Example	Explanation
'\u00d7'	Character literal, REF fixed 4 byte unicode 'char'. STD
b'x'	ASCII byte literal. REF

Comments

No comment.

Example	Explanation
//	Line comment, use these to document code flow or <i>internals</i> .
//!	Inner line doc comment BK EX REF for auto generated documentation.
///	Outer line doc comment, use these on types.
/* ... */	Block comment.
/*! ... */	Inner block doc comment.
/** ... */	Outer block doc comment.
```rust ... ```	In doc comments, include a <a href="#">doc test</a> (doc code running on <code>cargo test</code> ).
#	In doc tests, hide line from documentation (``` # <a href="#">use</a> x::hidden; ```).

## Miscellaneous

These sigils did not fit any other category but are good to know nonetheless.

Example	Explanation
!	Always empty <b>never type</b> .  <a href="#">BK</a> <a href="#">EX</a> <a href="#">STD</a> <a href="#">REF</a>
_	Unnamed variable binding, e.g., <code> x, _  {}</code> .
_x	Variable binding explicitly marked as unused.
1_234_567	Numeric separator for visual clarity.
1_u8	Type specifier for <b>numeric literals</b> <a href="#">EX</a> <a href="#">REF</a> (also <code>i8</code> , <code>u16</code> , ...).
0xBEEF, 0o777, 0b1001	Hexadecimal ( <code>0x</code> ), octal ( <code>0o</code> ) and binary ( <code>0b</code> ) integer literals.
r#foo	A <b>raw identifier</b> <a href="#">BK</a> <a href="#">EX</a> for edition compatibility.
x;	<b>Statement</b> <a href="#">REF</a> terminator, c. <b>expressions</b> <a href="#">EX</a> <a href="#">REF</a>

## Common Operators

Rust supports all common operators you would expect to find in a language (`+`, `*`, `%`, `=`, `==`...). Since they behave no differently in Rust we do not list them here. For some of them Rust also supports **operator overloading**. [STD](#)

# Standard Library

 This section is **WORK IN PROGRESS**. Comments, issues and PRs are very welcome. 

## Traits

## Common Markers

These traits mark **special properties** of the underlying type.

A type <code>T</code> marked ...	Means <code>T</code> can ...
<code>Copy</code>	Be copied bitwise; cheap & fast. Also means <code>x = t</code> will copy <code>t</code> instead of move.
<code>Clone</code>	Be explicitly duplicated via <code>.clone()</code> . Might be expensive.
<code>Send</code> *	Be moved between threads safely.
<code>Sync</code> *	Have its reference <code>&amp;T</code> sent between threads safely.
<code>Sized</code> *	Live on the stack and has a size known at compilation time.

* Automatically implemented by compiler where appropriate.

## String Conversions

If you **want** a string of type ...

String	CString	OSString	Vec<u8>	&str	&CStr	&[u8]	&[u16]	*const c_char
If you have <code>x</code> of type ...								Use this ...
<code>String</code>								<code>x.clone()</code>
<code>CString</code>								<code>x.into_string()?</code>
<code>OSString</code>								<code>x.to_str()?.into()</code>
<code>Vec&lt;u8&gt;</code> ¹								<code>String::from_utf8(x)?</code>
<code>&amp;str</code>								<code>x.into()</code>
<code>&amp;CStr</code>								<code>x.to_str()?.into()</code>
<code>&amp;OSStr</code>								<code>x.to_str()?.into()</code>
<code>&amp;[u8]</code> ¹								<code>String::from_utf8_lossy(x).into()</code>

¹ You should or must (if `unsafe` calls are involved) ensure the raw data comes with a valid representation for the string type (e.g., being UTF-8 encoded data for `String`).

## Guides

### Project Anatomy

Basic project layout, and common files and folders, as used by Rust [tooling](#).

Entry	Code
<code>benches/</code>	Benchmarks for your crate, run via <code>cargo bench</code> , requires nightly by default. * 
<code>examples/</code>	Examples how to use your crate, run via <code>cargo run --example my_example</code> .
<code>src/</code>	Actual source code for your project.

Entry	Code
<code>build.rs</code>	Pre-build script, e.g., when compiling C / FFI, needs to be specified in <code>Cargo.toml</code> .
<code>main.rs</code>	Default entry point for applications, this is what <code>cargo run</code> uses.
<code>lib.rs</code>	Default entry point for libraries. This is where lookup for <code>my_crate::f</code> starts.
<code>tests/</code>	Integration tests go here, invoked via <code>cargo test</code> . Unit tests often stay in <code>src/</code> file.
<code>.rustfmt.toml</code>	In case you want to <a href="#">customize</a> how <code>cargo fmt</code> works.
<code>.clippy.toml</code>	Special configuration for certain <a href="#">clippy lints</a> .
<code>Cargo.toml</code>	Main project configuration. Defines dependencies, artifacts ...
<code>Cargo.lock</code>	Dependency details for reproducible builds, recommended to <code>git</code> for apps, not for libs.

* On stable consider [Criterion](#).

## Idiomatic Rust

If you are used to programming Java or C, consider these.

Idiom	Code
<b>Think in Expressions</b>	<pre>x = if x { a } else { b };  x = loop { break 5 };  fn f() -&gt; u32 { 0 }</pre>
<b>Think in Iterators</b>	<pre>(1..10).map(f).collect()  names.iter().filter( x  x.starts_with("A"))</pre>
<b>Handle Absence with ?</b>	<pre>x = try_something?;  get_option()?.run()</pre>
<b>Use Strong Types</b>	<pre>enum E { Invalid, Valid { ... } } over ERROR_INVALID = -1  enum E { Visible, Hidden } over visible: bool  struct Charge(f32) over f32</pre>
<b>Provide Builders</b>	<code>Car::new("Model T").hp(20).run();</code>
<b>Split Implementations</b>	<p>Generic types <code>S&lt;T&gt;</code> can have a separate <code>impl</code> per <code>T</code>.</p> <p>Rust doesn't have OO, but with separate <code>impl</code> you can get specialization.</p>
<b>Unsafe</b>	Avoid <code>unsafe {}</code> , often safer, faster solution without it. Exception: FFI.
<b>Implement Traits</b>	<code>#[derive(Debug, Copy, ...)]</code> and custom <code>impl</code> where needed.
<b>Tooling</b>	<p>With <code>clippy</code> you can improve your code quality.</p> <p>Formatting with <code>rustfmt</code> helps others to read your code.</p>
	Add <code>unit tests</code> <small>BK</small> ( <code>#[test]</code> ) to ensure your code works.
	Add <code>doc tests</code> <small>BK</small> ( <code>``` my_api::f() ```</code> ) to ensure docs match code.
<b>Documentation</b>	<p>Annotate your APIs with doc comments that can show up on <a href="#">docs.rs</a>.</p> <p>Don't forget to include a <b>summary sentence</b> and the <b>Examples</b> heading.</p> <p>If applicable: <b>Panics, Errors, Safety, Abort</b> and <b>Undefined Behavior</b>.</p>

🔥 We **highly** recommend you also follow the [API Guidelines \(Checklist\)](#) for any shared project! 🔥

# Async-Await 101

If you are familiar with `async / await` in C# or TypeScript, here are some things to keep in mind:

Construct	Explanation
<code>async</code>	Anything declared <code>async</code> always returns an <code>impl Future&lt;Output=_&gt;</code> . ^{STD}
<code>async fn f()</code>	Function <code>f</code> returns an <code>impl Future&lt;Output=_&gt;</code> .
<code>async fn f() -&gt; S</code>	Function <code>f</code> returns an <code>impl Future&lt;Output=S&gt;</code> .
<code>async { x }</code>	Transforms <code>{ x }</code> into an <code>impl Future&lt;Output=X&gt;</code> .
<code>let sm = f();</code>	Calling <code>f()</code> that is <code>async</code> will <b>not</b> execute <code>f</code> , but produce state machine <code>sm</code> . ¹
<code>sm = async { g() };</code>	Likewise, does <b>not</b> execute the <code>{ g() }</code> block; produces state machine.
<code>runtime.block_on(sm);²</code>	Outside an <code>async {}</code> , schedules <code>sm</code> to actually run. Would execute <code>g()</code> .
<code>sm.await</code>	Inside an <code>async {}</code> , run <code>sm</code> until complete. Yield to runtime if <code>sm</code> not ready.

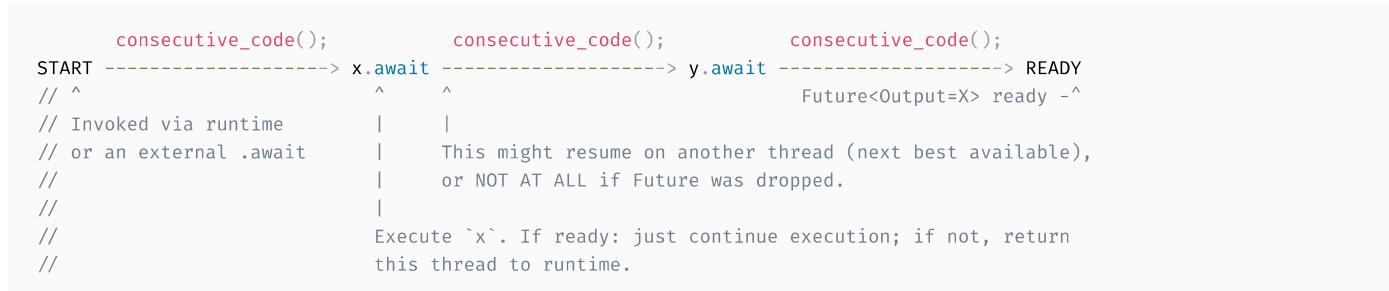

¹ Technically `async` transforms the following code into an anonymous, compiler-generated state machine type, and `f()` instantiates that machine. The state machine always `impl Future`, possibly `Send` & co, depending on types you used inside `async`. State machine driven by worker thread invoking `Future::poll()` via runtime directly, or parent `.await` indirectly.

² Right now Rust doesn't come with its own runtime. Use external crate instead, such as `async-std` or `tokio 0.2+`. Also, Futures in Rust are an MPV. There is **much** more utility stuff in the `futures` crate.

At each `x.await`, state machine passes control to subordinate state machine `x`. At some point a low-level state machine invoked via `.await` might not be ready. In that case worker thread returns all the way up to runtime so it can drive another Future. Some time later the runtime:

- **might** resume execution. It usually does, unless `sm / Future` dropped.
- **might** resume with the previous worker **or another** worker thread (depends on runtime).

Simplified diagram for code written inside an `async` block :

This leads to the following considerations when writing code inside an `async` construct:

Constructs ¹	Explanation
<code>sleep_or_block();</code>	Definitely bad ●, never halt current thread, clogs executor.
<code>set_TL(a); x.await; TL();</code>	Definitely bad ●, <code>await</code> may return from other thread, <code>thread local</code> invalid.
<code>s.no(); x.await; s.go();</code>	Maybe bad ●, <code>await</code> will <b>not return</b> if <code>Future</code> dropped while waiting. ²
<code>Rc::new(); x.await; rc();</code>	Non- <code>Send</code> types prevent <code>impl Future</code> from being <code>Send</code> ; less compatible.

¹ Here we assume `s` is any non-local that could temporarily be put into an invalid state; `TL` is any thread local storage, and that the `async {}` containing the code is written without assuming executor specifics.

² Since `Drop` is run in any case when `Future` is dropped, consider using drop guard that cleans up / fixes application state if it has to be left in bad condition across `.await` points.

## Closures in APIs

There is a subtrait relationship `Fn : FnMut : FnOnce`. That means, a closure that implements `Fn`, also implements `FnMut` and `FnOnce`. Likewise, a closure that implements `FnMut`, also implements `FnOnce`.

From a call site perspective that means:

Signature	Function <code>g</code> can call ...	Function <code>g</code> accepts ...
<code>g&lt;F: FnOnce()&gt;(f: F)</code>	... <code>f()</code> once.	<code>Fn, FnMut, FnOnce</code>
<code>g&lt;F: FnMut()&gt;(mut f: F)</code>	... <code>f()</code> multiple times.	<code>Fn, FnMut</code>
<code>g&lt;F: Fn()&gt;(f: F)</code>	... <code>f()</code> multiple times.	<code>Fn</code>

Notice how **asking** for a `Fn` closure as a function is most restrictive for the caller; but **having** a `Fn` closure as a caller is most compatible with any function.

From the perspective of someone defining a closure:

Closure	Implements*	Comment
<code>   { moved_s; }</code>	<code>FnOnce</code>	Caller must give up ownership of <code>moved_s</code> .
<code>   { &amp;mut s; }</code>	<code>FnOnce, FnMut</code>	Allows <code>g()</code> to change caller's local state <code>s</code> .
<code>   { &amp;s; }</code>	<code>FnOnce, FnMut, Fn</code>	May not mutate state; but can share and reuse <code>s</code> .

* Rust [prefers capturing](#) by reference (resulting in the most "compatible" `Fn` closures from a caller perspective), but can be forced to capture its environment by copy or move via the `move || {}` syntax.

That gives the following advantages and disadvantages:

Requiring	Advantage	Disadvantage
<code>F: FnOnce</code>	Easy to satisfy as caller.	Single use only, <code>g()</code> may call <code>f()</code> just once.
<code>F: FnMut</code>	Allows <code>g()</code> to change caller state.	Caller may not reuse captures during <code>g()</code> .
<code>F: Fn</code>	Many can exist at same time.	Hardest to produce for caller.

## A Guide to Reading Lifetimes

Lifetimes can be overwhelming at times. Here is a simplified guide on how to read and interpret constructs containing lifetimes if you are familiar with C.

Construct	How to read
<code>let s: S = S(0)</code>	A location that is <code>S</code> -sized, named <code>s</code> , and contains the value <code>S(0)</code> . If declared with <code>let</code> , that location lives on the stack. ¹
	Generally, <code>s</code> can mean <i>location of s</i> , and <i>value within s</i> .
	As a location, <code>s = S(1)</code> means, assign value <code>S(1)</code> to location <code>s</code> .
	As a value, <code>f(s)</code> means call <code>f</code> with value inside of <code>s</code> .
	To explicitly talk about its location (address) we do <code>&amp;s</code> .
	To explicitly talk about a location that can hold such a location we do <code>&amp;s</code> .
<code>&amp;'a S</code>	A <code>&amp;s</code> is a <b>location that can hold</b> (at least) <b>an address</b> , called reference. Any address stored in here must be that of a valid <code>s</code> .
	Any address stored must be proven to exist for at least ( <i>outline</i> ) duration <code>'a</code> . In other words, the <code>&amp;s</code> part sets bounds for what any address here must contain.
	While the <code>&amp;'a</code> part sets bounds for how long any such address must at least live.

Construct	How to read
	The lifetime our containing location is unrelated, but naturally always shorter.
<code>&amp;s</code>	<p>Duration of '<code>a</code>' is purely compile time view, based on static analysis.</p> <p>Sometimes '<code>a</code>' might be elided (or can't be specified) but it still exists.</p>
	Within methods bodies, lifetimes are determined automatically.
	Within signatures, lifetimes may be 'elided' (annotated automatically).
<code>&amp;s</code>	<p>This will produce the <b>actual address of location s</b>, called 'borrow'.</p> <p>The moment <code>&amp;s</code> is produced, location <code>s</code> is put into a <b>borrowed state</b>.</p>
	Checking if in borrowed state is based on compile-time analysis.
	This analysis is based on all possible address propagation paths.
	As long as <b>any</b> <code>&amp;s</code> could be around, <code>s</code> cannot be altered directly.
	For example, in <code>let a = &amp;s; let b = a;</code> , also <code>b</code> needs to go.
	Borrowing of <code>s</code> stops once last <code>&amp;s</code> is last used, not when <code>&amp;s</code> dropped.
<code>&amp;mut s</code>	<p>Same, but will produce a mutable borrow.</p> <p>A <code>&amp;mut</code> will allow the <i>owner of the borrow</i> (address) to change <code>s</code> content.</p>
	This reiterates that not the value in <code>s</code> , but location of <code>s</code> is borrowed.

¹ Compare [Data Structures](#) section above: while true for synchronous code, an `async` 'stack frame' might actually be placed on to the heap by the used async runtime.

When reading function or type signatures in particular:

Construct	How to read
<code>s&lt;'a&gt; {}</code>	<p>Signals that <code>s</code> will contain* at least one address (i.e., reference).</p> <p>'<code>a</code>' will be determined automatically by the user of this struct.</p>
	' <code>a</code> ' will be chosen as small as possible.
<code>f&lt;'a&gt;(x: &amp;'a T)</code>	<p>Signals this function will accept an address (i.e., reference).</p>
$\rightarrow \&'a S$	<p>... and that it returns one.</p>
	' <code>a</code> ' will be determined automatically by the caller.
	' <code>a</code> ' will be chosen as small as possible.
	' <code>a</code> ' will be picked so that it <b>satisfies input and output</b> at call site.
	More importantly, <b>propagate borrow state</b> according to lifetime names!
	So while result address with ' <code>a</code> ' is used, input address with ' <code>a</code> ' is locked.
	Here: while <code>s</code> from <code>let s = f(&amp;x)</code> is around, <code>x</code> counts as 'borrowed'.
<code>&lt;'a, 'b: 'a&gt;</code>	<p>The lifetimes declared in <code>s</code> and <code>f</code> can also have bounds.</p>
	The <code>&lt;'a, 'b&gt;</code> part means the type will handle at least 2 addresses.
	The ' <code>b: 'a</code> ' part is a <b>lifetime bound</b> , and means ' <code>b</code> must <b>outlive</b> ' <code>a</code> '.
	Any address in an <code>&amp;'b x</code> must exist at least as long as any in an <code>&amp;'a y</code> .

* Technically the struct may not hold any data (e.g., when using the '`a`' only for `PhantomData` or function pointers) but still make use of the '`a`' for communicating and requiring that some of its functions require reference of a certain lifetime.

## Invisible Sugar

If something works that "shouldn't work now that you think about it", it might be due to one of these.

Name	Description
<b>Coercions</b> <small>NOM</small>	'Weaken' types to match signature, e.g., <code>&amp;mut T</code> to <code>&amp;T</code> .
<b>Deref</b> <small>NOM</small>	<code>Deref x: T</code> until <code>*x, **x, ...</code> compatible with some target <code>s</code> .
<b>Prelude</b> <small>STD</small>	Automatic import of basic types.
<b>Reborrow</b>	Since <code>x: &amp;mut T</code> can't be copied; move new <code>&amp;mut *x</code> instead.
<b>Lifetime Elision</b> <small>BK NOM REF</small>	Automatically annotate <code>f(x: &amp;T)</code> to <code>f&lt;'a&gt;(x: &amp;'a T)</code> .
<b>Method Resolution</b> <small>REF</small>	Deref or borrow <code>x</code> until <code>x.f()</code> works.

## Unsafe, Unsound, Undefined

Unsafe leads to unsound. Unsound leads to undefined. Undefined leads to the dark side of the force.

Unsafe Code	Undefine Behavior	Unsound Code
<b>Unsafe Code</b>		

- Code marked `unsafe` has special permissions, e.g., to deref raw pointers, or invoke other `unsafe` functions.
- Along come special **promises the author must uphold to the compiler**, and the compiler *will trust you*.
- By itself `unsafe` code is not bad, but dangerous, and needed for FFI or exotic data structures.

```
// `x` must always point to race-free, valid, aligned, initialized u8 memory.
unsafe fn unsafe_f(x: *mut u8) {
 my_native_lib(x);
}
```

### Responsible use of Unsafe

- Do not use `unsafe` unless you absolutely have to.
- Follow the [Nomicon](#), [Unsafe Guidelines](#), **always** uphold **all** safety invariants, and **never** invoke [UB](#).
- Minimize the use of `unsafe` and encapsulate it in the small, sound modules that are easy to review.
- Each `unsafe` unit should be accompanied by plain-text reasoning outlining its safety.

## Formatting Strings

Formatting applies to `print!`, `eprint!`, `write!` (and their `-ln` siblings like `println!`). Each format argument is either empty `{}`, `{argument}`, or follows a basic [syntax](#):

```
{ [argument] ':' [[fill] align] [sign] ['#'] [width [$]] [. precision [$]] [type] }
```

Element	Meaning
---------	---------

Element	Meaning
argument	Number (0, 1, ...) or argument name, e.g., <code>print!("{}"</code> , x = 3).
fill	The character to fill empty spaces with (e.g., 0), if width is specified.
align	Left (<), center (^), or right (>), if width is specified.
sign	Can be + for sign to always be printed.
#	Alternate formatting, e.g. prettify Debug ? or prefix hex with 0x.
width	Minimum width ( $\geq 0$ ), padding with fill (default to space). If starts with 0, zero-padded.
precision	Decimal digits ( $\geq 0$ ) for numerics, or max width for non-numerics.
\$	Interpret width or precision as argument identifier instead to allow for dynamic formatting.
type	Debug (?) formatting, hex (x), binary (b), octal (o), pointer (p), exp (e) ... <a href="#">see more</a> .

Example	Explanation
{:?}	Print the next argument using Debug.
{2:#?}	Pretty-print the 3rd argument with Debug formatting.
{val:^2\$}	Center the val named argument, width specified by the 3rd argument.
{:<10.3}	Left align with width 10 and a precision of 3.
{val:#x}	Format val argument as hex, with a leading 0x (alternate format for x).

## Tooling

Some commands and tools that are good to know.

Command	Description
<code>cargo init</code>	Create a new project for the latest edition.
<code>cargo build</code>	Build the project in debug mode ( --release for all optimization).
<code>cargo check</code>	Check if project would compile (much faster).
<code>cargo test</code>	Run tests for the project.
<code>cargo run</code>	Run your project, if a binary is produced (main.rs).
<code>cargo doc --open</code>	Locally generate documentation for your code and dependencies.
<code>cargo rustc -- -Zunpretty=X</code>	Show more desugared Rust code, in particular with X being:
expanded	Show with expanded macros, ...
<code>cargo +{nightly, stable} ...</code>	Runs command with given toolchain, e.g., for 'nightly only' tools.
<code>rustup docs</code>	Open offline Rust documentation (incl. the books), good on a plane!

A command like `cargo build` means you can either type `cargo build` or just `cargo b`.

These are optional `rustup` components. Install them with `rustup component add [tool]`.

Tool	Description
<code>cargo clippy</code>	Additional ( <a href="#">lints</a> ) catching common API misuses and unidiomatic code. <a href="#">🔗</a>
<code>cargo fmt</code>	Automatic code formatter ( <code>rustup component add rustfmt</code> ). <a href="#">🔗</a>

A large number of additional cargo plugins [can be found here](#).
